1 Basic Knowledge

Def of expectation (Moments): For any well-behaved function h on $\mathbb{R}$. $\mathbb{E}[h(Y)] := \sum_i h(y_i)\mathbb{P}(Y = y_i)$ $\mathbb{E}[h(Y)] := \int_{\mathbb{R}} h(y) f_Y(y)dy$

Def of Model: A collection of distributions indexed by a parameter $\{F_{\mathbf{Y}}(\cdot|\theta); \theta \subseteq \Theta\}$ is model.

Likelihood Function: $L(\theta;\mathbf{y}) = f_{\mathbf{Y}}(\mathbf{y};\theta)$ ·**MLE**: $\hat{\theta}(\mathbf{y}) = ArgMax_{\theta\in\Theta}[L(\theta;\mathbf{y})] = [U(\hat{\theta}) = 0]$ ps: MLE has invariant property

(Strong) Likelihood Principle: $L(\theta;x) \propto L(\theta;y)$ [Strong: $L_f(\theta;x) \propto L_g(\theta;z)$; f, g are statistical model] $\Rightarrow$ Same Inferential Conclusions.

Def of Identifiability: A model is identifiable if $f(y;\theta_1) = f(y;\theta_2), \forall y$ then $\theta_1 = \theta_2$ (i.e.$map : \theta \to f(y;\theta)$ is 1-1)

Linear Algebra Knowledge: If A is symmetric matrix, with eigenvalues λ_n then $A + aI$ have eigenvalues $\lambda_n + a$. || $det(M) = \prod \lambda_n$ || eigenvalues of $X^T X \ge 0$.

· Method: **1**.By def ⇒ ratio not depend on $y \Rightarrow \theta_1, \theta_2$ relationship. (with any additional constraint) **2**.MLE not unique ⇒ not identifiable **3**.Give an example θ **4**.Fisher information

3 Bayesian Inference

3.1 Bayesian Approach & Definitions

Basic Idea: Consider $\underline{\theta}$ as a r.v.. Bayesian approach ⇒ Probability are used to represent degree of believe about the unknown $\underline{\theta}$

Prior Distribution $p(\underline{\theta})$: Prior distribution $p(\underline{\theta})$ contains all available prior information about $\underline{\theta}$ *before observing any data*.

· **Hyper-Parameters**: 由于 $p(\underline{\theta})$ 是已知, 服从某种分布 (with parameter γ). We denoted $p(\underline{\theta})$ as $p(\underline{\theta};\gamma)$ where γ is *Hyper-parameters*. 定义: $\gamma_{prior} \to \gamma_{post}$

Likelihood function $p(\mathbf{y}|\underline{\theta}) = f(\mathbf{y}|\underline{\theta})$: Any observed data is considered as a realisation of r.v. Y with $f(\mathbf{y}|\underline{\theta})$

Posterior Distribution $p(\underline{\theta}|\mathbf{y})$: Posterior distribution $p(\underline{\theta}|\mathbf{y})$, contains all available knowledge.

· **Bayes' Rule / Theorem**: $p(\underline{\theta}|\mathbf{y}) = \frac{p(\mathbf{y}|\underline{\theta})p(\underline{\theta})}{p(\mathbf{y})} = \frac{f(\mathbf{y}|\underline{\theta})p(\underline{\theta})}{m(\mathbf{y})}$ $\quad p(\mathbf{y}) = m(\mathbf{y}) = \int_{\underline{\theta}\in\Theta} f(\mathbf{y}|\underline{\theta})p(\underline{\theta})d\underline{\theta}$ (Normalizing constant)

Name	MAP Maximum A Posteriori	MMSE Posterior Mean / Bayesian Minimum Mean Squared Error Estimator	Posterior Median $\hat{\theta}_{median}$
Single Para	$\hat{\theta}_{MAP} = \arg\max_\theta p(\theta|\mathbf{y})$	$\hat{\theta}_{MMSE} = \mathbb{E}[\theta|\mathbf{y}] = \int_{\theta\in\Theta} \theta p(\theta|\mathbf{y})d\theta$	$\frac{1}{2} = \int_{-\infty}^{\hat{\theta}_{median}} p(\theta|\mathbf{y})d\theta = \int_{\hat{\theta}_{median}}^{\infty} p(\theta|\mathbf{y})d\theta$

Name	Posterior Var	$C_\alpha = [a,b]$ $(1-\alpha)100\%$ Bayesian Credible Intervals (or Simply Credible Intervals)
Single Para	$Var[\theta|\mathbf{y}] = \int_{\theta\in\Theta}(\theta - \mathbb{E}[\theta|\mathbf{y}])^2 p(\theta|\mathbf{y})d\theta$	$\mathbb{P}(a \le \theta \le b|\mathbf{y}) = \int_a^b p(\theta|\mathbf{y})d\theta = 1-\alpha$ ps: $\mathbb{P}(\theta < a|\mathbf{y}) = \mathbb{P}(\theta > b|\mathbf{y}) = \alpha/2$

Bayesian Decision Theory: 目的: [1]Estimating parameter θ [2]Test Hypothesis about θ [3]Find CI. ps: 后两种有很多种方法来判断

1. Choose a *Loss Function* $Q(\hat{\theta},\theta)$ (损失函数, 衡量估计值与真实值的差距; 贝叶斯决策的目的是最小化损失函数的期望)
2. Minimises Posterior Expacted Loss Function: $\hat{\theta}_Q(\mathbf{y}) = \arg\min_{\hat{\theta}} \mathbb{E}[Q(\hat{\theta},\theta)|\mathbf{y}] = \arg\min_{\hat{\theta}} \int_{\theta\in\Theta} Q(\hat{\theta},\theta)p(\theta|\mathbf{y})d\theta$

3.2 Exact Bayesian Inference with Conjugate priors

Conjugate Prior: For $\underline{\theta}$, $p(\underline{\theta})$ is *Conjugate Prior* for $p(\mathbf{y}|\underline{\theta}) = f(\mathbf{y}|\underline{\theta})$ iff 对 $p(\underline{\theta})$ 用 Bayes' Rule 得到的 $p(\mathbf{y}|\underline{\theta})$ 都在同一类型的分布

Conjugate Family: The collection of all *Conjugate Prior*.

Choice of Prior: Observed data number n: [1]n small ⇒ Posterior shows a great dependency of the choice of prior.

[2]n middle ⇒ posterior less affected by choice of prior. [3]n large ⇒ choice of prior has limited effect on posterior.(Likelihood has a strong impact)

Comparing the frequentist and Bayesian approaches: [1] $\hat{\theta}_{MMSE} \approx \hat{\theta}_{MAP}$ for most cases, especially n large. [2]n large: $\hat{\theta}_{MAP} \approx \hat{\theta}_{MLE}$, $CI \approx C_\alpha$

3.3 Approximate Bayesian Inference

Intractable Posterior: Non-Conjugate model. (not analytic, no closed-form)

Monte Carlo Methods: Any func $g(\underline{\theta})$ || $I_g = \int_{\underline{\theta}\in\Theta} g(\underline{\theta})p(\underline{\theta}|\mathbf{y})d\underline{\theta} \approx \frac{1}{M}\sum_{i=1}^M g(\underline{\theta}^{(i)}) \xrightarrow{a.s.} I_g$ $\quad \underline{\theta}^{(i)} \sim p(\underline{\theta}|\mathbf{y}), i = 1,...,M$

1. **Importance Sampling (IS)**: [1] Simulating samples from another distribution $q(\underline{\theta})$ (*Proposal Distribution*) Consistent, Biased for finite [2]$w^{(i)} = \frac{\pi(\underline{\theta}^{(i)};\mathbf{y})}{q(\underline{\theta}^{(i)})}$, $\pi(\underline{\theta};\mathbf{y}) = f(\mathbf{y}|\underline{\theta})p(\underline{\theta})$ [3] IS estimator: $\hat{I}_g^M = \sum_{i=1}^M g(\underline{\theta}^{(i)})\overline{w}^{(i)} \xrightarrow{a.s.} I_g$, Normalized Weight: $\overline{w}^{(i)} = \frac{w^{(i)}}{\sum_{j=1}^M w^{(j)}}$ $\quad \underline{\theta}^{(i)} \sim q(\underline{\theta})$ ps: $\sum_{j=1}^M \overline{w}^{(j)} = 1$

   Remark: Choice of $q(\underline{\theta})$ is important. || $\hat{I}_g^M$ depends on: [1]# of M; [2]mismatch between proposal and the integrand of the integral. Good if $q(\underline{\theta}) \propto g(\underline{\theta})p(\underline{\theta}|\mathbf{y})$, difficult to achieve.:(

2. **Markov Chain Monte Carlo (MCMC)**: MCMC 算法通过 Markov Chain 生成样本, 使得样本接近服从后验分布.(计算量大)

Laplace Approximation: (最简单的估算 posterior 的方法) $p(\underline{\theta}|\mathbf{y}) \approx \mathcal{N}(\underline{\theta}_{MAP}; H^{-1}(\underline{\theta}_{MAP}))$ 类似 MLE 的 J $\quad H(\underline{\theta}) = -\frac{d^2 ln(p(\theta|\mathbf{y}))}{d\theta^2}$ (适合 $p(\underline{\theta}|\mathbf{y})$ 接近正态分布的时用)

Variational Inference (VI): [1]Choose $q(\underline{\theta};\underline{\eta})$, $\underline{\eta}$ 是 q 的参数. [2] 选择衡量 $p(\underline{\theta}|\mathbf{y})$, $q(\underline{\theta};\underline{\eta})$ 差异的方法 e.g.**KL divergence**: $KL(q(\underline{\theta};\underline{\eta})||p(\underline{\theta}|\mathbf{y})) = \int_{\theta\in\Theta} q(\underline{\theta};\underline{\eta})ln(\frac{q(\theta;\eta)}{p(\theta|\mathbf{y})})d\underline{\theta}$

[3] 优化参数 (Find parameters to minimise the divergence): $\underline{\eta}^* = \arg\min_{\eta\in A_\eta} KL(q(\underline{\theta};\underline{\eta})||p(\underline{\theta}|\mathbf{y}))$ [4]$p(\underline{\theta}|\mathbf{y}) \approx q(\underline{\theta};\underline{\eta}^*)$

Remark: Both Laplace Approximation & Variation Inference approximate $p(\underline{\theta}|\mathbf{y})$ by a parameter family of distributions. || 拉普拉斯是正态分布家族,VI 是更普遍的分布家族

Law of Total Probability: $\mathbb{P}(A) = \sum_n \mathbb{P}(A|B_n)\mathbb{P}(B_n)$, $\cup_n B_n = \Omega$, B_n disjoint

Type	Type I error	Type II error
Def	$\mathbb{P}(Rej\ H_0 \mid H_0\ is\ T)$	$\mathbb{P}(Fail\ Rej\ H_0 \mid H_0\ is\ F)$

-	H_0 is T	H_0 is F
Fail to Rej H_0	Right	Type II (β) 与 size 有关
Rej H_0	Type I (α) 与 size 无关	Right (Power)

Significance Level: $\alpha = \mathbb{P}(Rej\ H_0 \mid H_0\ is\ T)$

P-value: 1.One-side: $p = \mathbb{P}(T \geq t; T \sim H_0)$ 2.Two-sides: $p = 2\min\{\mathbb{P}(T \geq t; T \sim H_0), \mathbb{P}(T \leq t; T \sim H_0)\}$

Power of Test: $\mathbb{P}$(Rej $H_0|H_0$ is F)$= 1 - \beta = \mathbb{P}(Z \in C \mid \mu = \mu^*)$ · 1.Sample size ↑, Power ↑; 2.σ^2 ↓, Power ↑; 3.Effect size $|\theta_0 - \theta^*|$ ↑, Power ↑; 4.α↑, Power ↑.

Def of Confidence Interval (CI): $100(1-\alpha)\%$ Confidence Interval for θ is $[l(X), u(X)]$, $\mathbb{P}(l(X) < \theta < u(X)) = 1 - \alpha$.

(Convergence of r.v.) Name	Definition	written as	Example	
Convergence in Probability	If $\lim F_{X_n}(x) = F_X(x)$ for all $x \in \mathbb{R}$.	$X_n \xrightarrow{d} X$ or $X_n \xrightarrow{d} F_X$	CLT 最弱:	见下面
Convergence in Distribution	If $\forall \epsilon > 0, \lim \mathbb{P}(\|X_n - X\| > \epsilon) = 0.$	$X_n \xrightarrow{p} X$	WLLN 中等:	If $X_i \overset{i.i.d.}{\sim} F_X, \mathbb{E}[X_i] = \mu.$ $\Rightarrow \bar{X}_n \xrightarrow{p} \mu$
Almost Sure Convergence	If $\mathbb{P}(\lim X_n = X) = 1$	$X_n \xrightarrow{a.s.} X$	SLLN 最强:	If $X_i \overset{i.i.d.}{\sim} F_X, \mathbb{E}[X_i] = \mu,$ $Var[X_i] < \infty. \Rightarrow \bar{X}_n \xrightarrow{a.s.} \mu$

Central Limit Theorem (CLT): If $X_i \overset{i.i.d.}{\sim} F_X, \mathbb{E}[X_i] = \mu$ and $Var[X_i] < \infty$. $\Rightarrow \frac{\bar{X}_n - \mu}{\sqrt{\sigma^2/n}} = \frac{\sqrt{n}(\bar{X}_n - \mu)}{\sigma} \overset{d}{\sim} N(0,1)$ 样本均值的分布会趋近于正态分布

7 Writting Format

Distribution: 产生新 distribution 的一种方法: 通过条件概率来. $\mathbb{P}(A|B) = \mathbb{P}[(A \cap B)/B]$

p-value: p-value measures the plausibility that the data were generated under H_0. **Low p-value**: low p-value suggests H_0 is incompatible with the data and hence likely to be false.

CI: The set of values (e.g.θ) are not rejected at significance level α under H_0. If data are generated under H_0, there is a probability $(1-\alpha)$ for the true θ_0 to be within the $(1-\alpha)100\%$ CI.

Hypothesis Testing: **Steps**: ^{1} State H_0, H_1; ^{2} Select Test Statistic T; ^{3} distribution of T under H_0; ^{4} observed test statistic; ^{5} critical value / region, p-value, or CI; ^{6} conclusion. || **Reject** H_0: We would reject H_0 in favour of the H_1. (So that ...) || **Fail to reject** H_0: We fail to reject H_0. Hence, there is strong evidence against the null hypothesis.

MLE: **Using (Compare) Newton's Method = (≠) Scoring Method**: Because the second derivative of likelihood function doesn't (does) include the r.v.

MLE Inference Parameter|$\mathbb{P}(\theta < ?) = \alpha$ is false: We cannot make such probability statement. $\{\theta\}$ is a fixed value (but unknown).

Geoemtric Comparison of T_{Score},T_{Wald},T_{LR}: **1.**T_{Score} (Slope Comparison): Represents the slope of the likelihood function at θ_0; A steeper slope indicates that the likelihood function is changing more rapidly at $theta_0$, which implies a greater difference between $\hat{\theta}$ and θ_0. || **2.**T_{Wald} (Width Comparison): Compares the difference between $\hat{\theta}$ and θ_0. || **3.**T_{LR} (Height Comparison): Compares the maximum likelihood value $L(\hat{\theta})$ and the likelihood value at $\theta_0, L(\theta_0)$. A larger height difference indicates a greater discrepancy between $\hat{\theta}$ and θ_0 || T_{Score},T_{Wald},T_{LR} **Other 部分公式可以近似的理由**: This is due to $\hat{\theta}$ being a consistent estiamtor of θ_0, and $J(\theta_0)$ being a consistent estimator of $\mathcal{I}(\theta_0)$

Normal Linear Regression Assumptions: Assumptions are that the obervations: 1. are from a normal distribution; 2. are independent; 3. have a common variance; 4. Linearity of the expectation variable.

Linear Model: **LS Estimation**: $S(\beta)$ small: μ_i relatively close to the y_i; Large: μ_i far from their corresponding y_i. || **Meaning of** ε: The random component of the model is intended to capture the fact that if we gathered a replicate set of data, the β_i (coefficient) would not change, but the Y_i would, as a result of different measurement errors. || **Why Use Least Square to estimate** $\underline{\beta}$: Most of time, Linear Model can be a system of n equations with p parameters with $n > p$. In this case, the system is overdetermined and there is no exact solution. The least square method is used to find the best solution. || **Geometric Interpretation of Linear Model|LS Method**: The least Square Estimation of Linear Model amounts to finding the *orthogonal projection* of the n dimensional response data **y** onto the p dimensional linear subspace spanned by the columns of **X**. || **Geometric Interpretation of Linear Model|$\mathbb{E}$[y]**: $\mathbb{E}$[**y**] lies in the space spanned by the columns of **X**, | and the least square estimate seeks to find the point in this space that is closest to **y**. || **Independent of $\underline{\hat{\beta}}$, $\hat{\sigma}^2$**: **f**, **r** independent ⇒ $\underline{\hat{\beta}}$, $\hat{\sigma}^2$ independent.

Meaning of R^2: R^2 evaluates how weel the model fits the response data. || 后面减去的部分: proportion of the variance in the response variable that is not explained by the model. || **→1**: A value close to 1 indicates that the model fits well and can explain most of the variability. || **→ 0**: ⋆ a low R^2 value does *not necessarily* indicate a poor model; it may simply mean that the data contains a substantial random component.

For Model of Factors: If it's a model of Factors, it's often difficult to interpret the p-value for individual coefficients in any meaningful way. ⇒ Prefer to test the whole factor effect.
